

Q. What Is Stored Procedure?

A stored procedure is a group of SQL statements that form a logical unit and perform a particular task. Stored procedures are used to encapsulate a set of operations or queries to execute on a database server. For example, operations on an employee database (hire, fire, promote, lookup) could be coded as stored procedures executed by application code. Stored procedures can be compiled and executed with different parameters and results, and they may have any combination of input, output, and input/output parameters.

Q. What are the purposes and advantages of stored procedures?

Purposes and advantages of stored procedures:

- Manage, control and validate data
- It can also be used for access mechanisms
- Large queries can be avoided
- Reduces network traffic since they need not be recompiled
- Even though the stored procedure itself may be a complex piece of code, we need not write it over and over again. Hence stored procedures increase the reusability of code
- Permissions can be granted for stored procedures. Hence, increases security.

Q. Determine when to use stored procedures to complete SQL Server tasks?

- If a large piece of code needs to be performed repeatedly, stored procedures are ideal
- When hundreds of lines of SQL code need to be sent; it is better to use stored procedure through a single statement that executes the code in a procedure, rather than by sending hundreds of lines of code over the network.
- When security is required.

Q. Explain About The Process Which Takes Place To Execute A Stored Routine?

Answer :

CREATE PROCEDURE and CREATE FUNCTION statements are used to create a stored routines. It can act as a function or a procedure. A procedure can be called by using a call statement and passing output with the help of output variables. It can call other Stored routines and it can be called from the inside of a statement.

Q. Where The Procedures Are Stored In the Database?

A stored procedure is a subroutine available to applications accessing a relational database system. Stored procedures (sometimes called a proc, sproc, StoPro, or SP) are actually stored in the database data dictionary

Q. How Many Types Of Stored Procedure?

Stored Procedures is of two types

1. user define stored procedure
2. The system defines Stored procedure.

Q. Explain The Benefits Of Running Stored Procedure On A Database Engine?

Answer :

Stored procedures can run directly on a database engine. In industries where automation is the key, a stored procedure can run entirely on the database provided to it and this runs on a specialized database server. Network communication can be avoided. Also, this procedure is useful for the execution of complex SQL statements.

Q. Does Storing Of Data In Stored Procedures Increase The Access Time? Explain?

Answer :

Data stored in stored procedures can be retrieved much faster than the data stored in SQL database. Data can be precompiled and stored in Stored procedures. This reduces the time gap between query and compiling as the data has been precompiled and stored in the procedure. To avoid the repetitive nature of the database statement caches are used.

Q. What Are The Uses Of Stored Procedure?

Answer :

Stored procedures are often used for data validation and as access control mechanisms. The logic applied in applications can be centralized and stored in applications. Complex procedures and functionalities which require a huge amount of data processing and logic implementation access their data by procedures. Data is stored in these procedures and accessed by procedures.
